Amblyopia

Amblyopia (am-blee-OH-pee-a) is also known as "lazy eye" or “lazy vision.” The vision in the amblyopic eye is weaker than the vision in the "good eye," and cannot be corrected with glasses. In amblyopia, the pathway that carries the vision from the eye to the brain does not fully develop, and the brain ignores signals sent from the weaker eye. Although your child's eyes may look normal, he or she may still have “lazy eye.” The best way amblyopia can be found is with a complete eye exam.

Treatment

Amblyopia is treated by covering the “good eye” with a patch for several hours a day. This will make the “lazy eye” start working. The patch must be worn while the child is awake. The earlier treatment is started, the better the visual outcome will be.

It is hard to tell how long your child will need to wear an eye patch. For most children, the treatment takes several months to a year. Usually, the doctor will slowly decrease the number of hours the patch is worn until the vision stops changing.

It is very important to patch your child’s eye as directed and to keep all follow-up appointments. The earlier “lazy eye” is treated, the easier treatment will be.

How to put on a sticky eye patch

- Remove the paper backing. The side that goes next to the skin will be sticky like a Band Aid.
- Have your child close his or her eyes.
- Gently place the narrow end of the patch toward your child's nose (Picture 1). If your child wears glasses, put the patch directly over the eye (glasses are worn over the patch).
- There are also cloth patches that attach to glasses.
How to put on a sticky eye patch, continued

- Put the patch on the _______ eye for _______ hours each day. Do not count sleeping hours as patching time.
- Remove the patch at bedtime.

If you have trouble getting your child to keep the patch on or if you have any questions, be sure to ask your doctor or nurse. You may also contact:
